

Peak shaving chemical energy storage power station

Overview

Peak shaving is the process of reducing a facility's maximum power demand during periods when electricity prices are highest, typically late afternoon. An energy storage system discharges its stored energy during these peak times, reducing the need to draw expensive power from the grid. Energy and facility managers will gain valuable insights into how peak shaving applications can help unlock the full potential of energy storage systems. In an era of rising electricity costs, unpredictable peak demand charges, and growing pressure for energy independence, peak shaving energy storage is no longer a luxury. Peak shaving refers to reducing energy use during the grid's peak demand. Peak demand occurs in the morning and evening, straining the grid and risking outages when supply can't meet demand. These facilities store energy when demand is low and discharge it during peak times. By managing peak demand through smarter scheduling or energy storage, facilities can lower bills predictably, improve operational stability, and reduce stress on the local grid.
